

Density

Density is a fine textured Buffalograss primarily developed for its superior turf quality which allows for faster, easier harvesting and planting. It is ideal for residential, commercial, and industrial sites.

Density produces a lush, dense turf. It has good green color. Density is a female buffalograss, but has some male flowers mixed in. Landscapers will enjoy a much stronger sod block than Buffalograsses of the past. Density also shows promise in higher humidity and rainfall areas.

Characteristics: Density is compatible with a wide range of soil conditions. In the past, Buffalos were very thin and did not produce easily handled block sod. Density is not your typical Buffalo. Expect an excellent, dense turf that holds well in a block and does not have the weed invasion problems associated with other Buffalograsses.

Installation and Maintenance: Density can not be grown from seed. Therefore, it must be planted as plugs, sprigs, or sod. Sprig planting is recommended only for experienced landscapers. Plugs are our preferred planting method for those of you who can not solid sod your site. Solid sodding is, by far, the best way to go.

Water the grass as you plant it. Do not wait until the entire site is planted to water.

The site should be watered heavily for at least two weeks to promote establishment. After establishment period is over watering and mowing can be kept very minimal for a "native" look. A lush, manicured look may be achieved with increased water and maintenance.

Recommended mowing height, with a rotary mower, is 2 inches.

Recommended annual fertilization rate is one to two pounds Nitrogen per 1,000 square feet. Use split applications with one pound Nitrogen in the spring to encourage new growth and one pound of nitrogen in mid-to-late summer to promote healthy growth into the fall and winter.
